Spring Java Config

Craig Kelly

November 16, 2015

XML Config for us today

- Fairly standard XML file detailing the beans we need
- Generally fine, but any “dynamic” action is limited to factory beans and the like

```
<bean id="mainBean" class="demo.com.fedex.devframework.BigBean">
    <property name="neededBean" ref="otherBean" />
</bean>

<bean id="otherBean" class="demo.com.fedex.devframework.SubBean">
    <property name="name" value="A" />
</bean>
```

Autowiring is Cool, too

- Annotated classes are "auto-wired" on context startup
- Much of the configuration is inferred by scanning for annotated classes

Want More Info?

See Raja's presentations on Spring Annotations!

Java Config is an alternative

- Replace the XML file with a Java class
- Get all the power of executing custom Java code at context startup
- Compatible with existing XML config and Autowiring

```
@Configuration
public class JavaAppContext {
    @Bean
    public BigBean mainBean() {
        BigBean bean = new BigBean();
        bean.setNeededBean(childBean());
        return bean;
    }

    @Bean
    public SubBean childBean1() {
        SubBean bean = new SubBean();
        bean.setName("A");
        return bean;
    }
}
```

Basic Annotations

- @Configuration is used to annotate a class and specify that it can be used for configuring a context
- @Bean is used to annotate a method indicating that the method creates a bean

Build Alert

Using these annotations means that you WILL need cglib

Some Restrictions

- @Configuration classes must be non-final
- @Configuration classes must be non-local (may not be declared within a method)
- @Configuration classes must have a default/no-arg constructor and
- @Configuration classes may not use @Autowired constructor parameters.
- Any nested configuration classes in a @Configuration class must be static

Loading the Context

If you can load a context with XML, then there is an alternative for Java Config. Take the simplest example:

```
ApplicationContext ctx;
ctx = new ClassPathXmlApplicationContext("applicationContext.xml");
ctx.getBean("mainBean", SomeMainClass.class).doStuff();
```

There is an equivalent for Java Config. Let's assume that the Java class that contains our context configuration is named JavaAppContext.

```
ApplicationContext ctx;
ctx = new AnnotationConfigApplicationContext(JavaAppContext.class);
ctx.getBean("mainBean", SomeMainClass.class).doStuff();
```

Spring Magic for Java Config, Part 1

Consider this example. There are only two instances in the context: the catHat bean, and the someThing bean. The catHat bean has two references to the **same** instance of someThing.

```
<bean id="someThing" class="demo.com.fedex.Thing" />

<bean id="catHat" class="demo.com.fedex.CatInTheHat">
    <property name="thingOne" ref="someThing" />
    <property name="thingTwo" ref="someThing" />
</bean>
```

Spring Magic for Java Config, Part 2

Here's the same example done with Java Config. someThing appears to be called twice, so you might expect the catHat bean to have two different objects. Luckily, the Spring annotation handles this so our Java code "behaves" like the XML context. *

```
@Configuration
public class JavaAppContext {
    @Bean
    public Thing someThing() {
        return new Thing();
    }

    @Bean
    public CatInTheHat catHat() {
        CatInTheHat bean = new CatInTheHat();
        bean.setThingOne(someThing());
        bean.setThingTwo(someThing());
        return bean;
    }
}
```

*Yes, I realize that this is also a radical reinterpretation of a classic piece of literature.

Sample Project

A sample project is available demostrating all of the above. There is even a unit test demonstrating that an XML context and a Java Config context produce the same results. The sample project will be available in the same directory that you found this presentation.

Build Alert

It's a Maven project!
